Network Layer — DNS Misconfiguration

Action Performed

1. Opened **Network Connections** (`ncpa.cpl`) and accessed the active network adapter's **Internet Protocol Version 4 (TCP/IPv4)** properties.
2. Switched DNS configuration from automatic to manual and set the **Preferred DNS server** to `192.0.2.1` (an unroutable TEST-NET-1 address).

Verification & Findings

Symptom	The physical link remained active (*Up*), but hostname resolution failed across the network.
Diagnostic Check	Ran `nslookup` in Command Prompt, confirming standard DNS query timeouts. On an Active Directory Domain Controller, this condition triggers **Netlogon Event ID 5774** (failure to register SRV resource records).
